EMBL
It runs in the family

EMBL researchers have unveiled the first detailed 3D structure of the replication machinery – the polymerase – of the La Crosse orthobunyavirus (LACV). This virus causes human encephalitis but is a member of the same family as the flu virus, and the structure shows that the LACV polymerase has striking similarities to influenza virus polymerase.

These segmented negative-strand RNA viruses have a very specific way of making their mRNA: they ‘snatch’ a ‘cap’ of genetic material from the host cell mRNA and insert it into their own. This sets them apart from other groups of viruses, but also suggests that the complex machinery required to do this is likely to be common to them all.

That is exactly what the researchers found: the polymerase of the LACV looks very similar to that of the influenza virus. This level of detail has allowed the team to deduce how the polymerase functions in LACV and also to give new insight into the influenza polymerase. The team hopes that by understanding the structural and functional similarities across the whole group, promising drug compounds could be adapted to other related viruses.

CERN
Winners of the 2015 beamline for schools competition announced

In June, CERN announced the winners of its 2015 beamline for schools competition. Two teams of high-school students will travel to CERN in September to carry out their own experiments using a CERN accelerator beam. The winners, the Leo4G team from Liceo Scientifico Leonardo da Vinci School in Florence, Italy, and the Accelerating Africa team from St John’s College and Barnato Park High School in Johannesburg, South Africa, were selected from 119 teams from around the world.

The aim of the competition is to make a fully equipped beamline available for high-school students to run an experiment in the same way that researchers do at the Large Hadron Collider and other CERN facilities. In proposals of fewer than 1000 words, teams had to explain why they wanted to come to CERN, what they hoped to take away from the experience, and how they would use the particle beam for their experiment. They also had to summarise their written proposal in a creative and entertaining video.

Based in Geneva, Switzerland, CERN is the world’s largest particle physics laboratory. To learn more, see: www.cern.ch

More opportunities for teachers in Noordwijk

After a successful and expanded summer school for teachers (see the next issue for a full report), ESA is once again organising a training workshop for science teachers in association with the Galileo Teacher Training Programme. A diverse workshop programme consisting of practical sessions and lectures from ESA experts will allow participants to explore innovative ways to use space science and astronomy in the classroom to engage students. One of the main topics this year is cosmic light in celebration of the International Year of Light. Participants will also find out more about ESA education activities and resources, as well as the latest from ESA space science and astronomy missions.

The workshop will be held at the European Space Research and Technology Centre (ESTEC) in Noordwijk, the Netherlands, between 23 and 27 November 2015. The deadline for receipt of applications is 09:00 CEST on 21 September 2015. To find out more and apply, visit: http://sci.esa.int/education/56231-esagttp-teacher-training-workshop-2015-apply-now/

ESA is Europe’s gateway to space, with its headquarters in Paris, France. For more information, see: www.esa.int

Applications for the ESO astronomy camp 2015 are now open

Would your students like to spend a week in the Italian Alps carrying out astronomy activities with other friends of their age and become part of a vibrant international community of alumni and astronomers?

ESO is currently receiving applications for their next Astronomy camp, to take place during the Christmas holidays between Friday 26 December 2015 and Thursday 1 January 2016. The camp will be held at the Astronomical Observatory of the Autonomous Region of the Aosta Valley, Nus, Italy, close to some of Europe’s highest mountains and under a clear sky. The camp will explore the theme of the Solar System and exoplanets via several astronomical sessions, including lectures, hands-on activities and night-time observations using the Observatory telescopes, alongside various social activities, winter sports and excursions.

To register, applicants should fill in an online form and upload a video (maximum 3 minutes) on the theme ‘My favourite astronomical object/phenomenon’ by 4 October. Full details, and the form, can be found at: www.sterrenlab.com/camps/eso-astronomy-camp-2015/

ESO is the world’s most productive ground-based astronomical observatory, with its headquarters in Garching, near Munich in Germany, and its telescopes in Chile. For more information, see: www.eso.org

Towards safer illumination of paintings

Experiments at ESRF indicate that art galleries and museums should minimise their paintings’ exposure to violet-blue-green as much as possible for the safe display of paintings containing chrome yellows. Knowledge of the effect of visible light on light-sensitive pigments such as chrome yellows is of great importance for the long-term conservation of unique masterpieces, including those by Vincent van Gogh. A combination of high spatial resolution spectroscopic methods and electron paramagnetic resonance at ESRF allowed a team of scientists from Italy and Belgium to establish that visible light of a blue-green colour is the most effective in stimulating the darkening process of chrome yellows. This occurs via a Cr(VI)→Cr(III) reduction process that also involves Cr(V)-species as intermediates.

For the fuller story, read the ESRF news article at:

EUROfusion

JET-Set: experiments with tritium

There is a ripple of excitement in the fusion community, thanks to a batch of tritium that has reached the Culham Centre for Fusion Energy, UK, which houses JET, Europe’s largest fusion device. The use of tritium, a heavy, unstable isotope of hydrogen, is crucial to the development of fusion power plants that might provide clean and abundant energy in the future.

Researchers know that the most efficient fuel for a fusion power plant is a mix of tritium and deuterium, another heavy hydrogen isotope that is available from sea water. But what will the exact results be when the mixture is used in the JET vessel? That is what the fusion community wants to test. So far, the JET fusion experiments in the renovated vessel have been fuelled with ‘regular’ hydrogen and deuterium. Researchers can now test the influence of the tritium–deuterium fuel on plasma performance and on interactions between the plasma and the renovated JET wall.

In many ways, the JET experiments are a test run for ITER, the next generation fusion experiment, which is currently being built in France. ITER will be the first magnetic confinement device to produce a net surplus of fusion energy and to demonstrate the main technologies for a fusion power plant. The deuterium–tritium experiment in JET will provide an important step to gain experience and train a new generation of engineers and scientists.

To learn more, see the story “JET’s next tritium experiments materialise” on the EUROfusion website, scan the QR code or visit: www.euro-fusion.org/2015/06/jets-next-tritium-experiments-materialise/

EUROfusion comprises 28 European member states as well as Switzerland and manages fusion research activities on behalf of Euratom. The aim is to realize fusion electricity by 2050. See www.euro-fusion.org

Light-sensitive chrome yellow paints exposed to different wavelengths of monochromatic light.
Alzheimer’s disease markers could be identified through protein water mobility, suggest ILL scientists. A study of water mobility on the surface of tau protein fibres, one of the pathological hallmarks of Alzheimer’s disease, has been conducted by a global team of scientists using neutron scattering experiments at the Institut Laue-Langevin (ILL) in Grenoble, France, and the Jülich Centre for Neutron Science at the Heinz Maier-Leibnitz-Zentrum (MLZ) in Garching, Germany. The team found that water mobility on the surface of tau protein fibres is increased compared to non-aggregated tau proteins. The findings, reported in the journal Proceedings of the National Academy of Sciences of the United States of America, suggest that the movement of water molecules could be a marker for the presence of amyloid tau fibres and could contribute to the detection of Alzheimer’s disease.
