Simulating the effect of the solar wind

The smooth operation of communications satellites can be influenced by solar weather. Mimic this effect on a smaller scale in the classroom with a simple demonstration.

By Theodoros Pierratos, Paraskevi Tsakmaki and Christos Papageorgiou

It’s the final of the 2014 football World Cup, the score is tied and there is no time left on the clock. Fans all over the world hold their breath, but suddenly all the TV sets in Europe go black! What can cause this to happen?

Keeping connected

Let’s start from the beginning. How is it possible to watch, almost in real time, an event taking place thousands of kilometres away? The answer orbits above our heads: satellites.
Solar wind and satellites
The solar wind is a stream of charged particles, mainly electrons and protons, that are released from the very hot corona, the upper atmosphere of the Sun. The particles escape the Sun’s gravity because of their high kinetic energy. This stream of particles reaching Earth varies in density, temperature and speed, depending on time and longitude.

When these particles approach Earth, they can have various effects: from spectacular aurorae to great geomagnetic storms. As geostationary satellites are near the edge of Earth’s protective magnetism, they can be exposed to these storms.

In the classroom
The effect of the solar wind on telecommunications is a modern issue that can trigger students’ interest in space technology and space weather. But how can we mimic it in the classroom? How can we simulate the solar wind? The Fun Fly Stick toy (figure 1) is a portable wand-like version of the Van de Graaff generator. When switched on, a belt moves inside the Fun Fly Stick and a static charge builds on the wand. Instead of the metal dome of the Van de Graaff generator, the charge accumulates on a cardboard tube. Cardboard has a high electrical resistivity but becomes a conductor when subjected to high-voltage electricity. Furthermore, it discharges more slowly than metal, so the shocking discharge sensation is eliminated.

We can safely use this toy to simulate solar wind by placing a large needle or thin metal axle on the end of the control tube (figure 2). Positive electrostatic charges formed on the cardboard tube are concentrated at the tip of the needle and so ionise the air nearby. Negative ions in the air will rush towards the needle tip and positive ions will move away due to electrostatic repulsion. The movement of these ions creates a form of an ‘electric wind’ or, for the purpose of our simulation, a ‘solar wind’.

To demonstrate the effect of the
Teaching activities

laboratory-made solar wind, we can just use a test screwdriver. Ask your students to imagine that the simple electrical circuit built into this screwdriver (usually including a battery supply and a red LED) is part of the electronic equipment of an orbiting satellite transmitting their favourite TV show. What will happen if we turn on the generator and come close (about 1 metre or less) to the test screwdriver? The red LED starts glowing (figure 3), and as the stick approaches the screwdriver it glows more and more brightly! The electric circuit starts to overload. What could be the effects of a solar storm on the electronic circuits of a satellite?

Carrying sound on a light beam

As well as overloading and possibly damaging the electronic circuits in a satellite, the solar wind could disrupt the live streaming of the World Cup final. To show this experimentally, we first have to observe that electromagnetic waves can carry usable information. To do this, we propose a modified version of the experiment described by Bernardelli, 2010 (figure 4).

Instead of using a laser pointer and a photo-diode, we use a LED flashlight (torch) and a small solar panel! In this way, we reduce the distance that the sound is transmitted but make a stronger impression on the students:

most of them consider a laser beam to be something special, but by using a normal flashlight, we can focus on the science behind the phenomenon (box 1).

With the screwdriver demonstration above, we showed that the solar wind could overload and probably damage a subtle electronic circuit on board a telecommunications satellite. To repeat our classroom simulation without ruining equipment, we designed and built a simple electronic circuit (box 2).

The concepts of space weather and satellite technology are not part of the curriculum, at least not in Greece. However, space-related topics can increase students’ interest in science (Spencer & Hulbert, 2006). An obvious problem for teachers is how to demonstrate effects of this scale and intensity in a classroom. In this article, we hope to convince you that all it takes is a toy and some basic skills in constructing a simple electronic circuit.

Carrying sound on a light beam

Materials

Transmitter
- LED flashlight (torch)
- 2 alligator clips
- 3.5 mm stereo plug
- Breadboard
- 100 Ω resistor
- 100 μF capacitor
- Mp3 player with a 3.5 mm jack output
- Battery holder
- 3 1.5 V batteries (depending on the flashlight you use)
- Soldering iron
- Solder
- 2 small pieces of lighting flex wire (about 3 cm each)

Receiver
- Solar panel
- Amplifying speakers with external power supply
- 2 alligator clips

Procedure

The transmitter
1. Unscrew the head of the flashlight (figure 5).
2. Use the breadboard to construct the circuit shown in figure 6. Your circuit should look like the one in figure 4 (instead of using a breadboard, you can construct the circuit using alligator clips to make the proper connections). Be careful to connect the head of the flashlight and the battery holder exactly as it looks in figure 7. The negative pole of the battery holder (black wire) must be connected with the side body of the flashlight’s head while the positive pole (red wire) must be connected with the spring-like metal in the centre of the head. Otherwise, the flashlight will not turn on.
3. To connect the stereo plug to the breadboard, solder the two pieces of wire to the stereo plug. Solder one wire (red) to both the first and second segments of the plug (or in just one of them) while the other wire (white) goes to the third segment (figure 8).

Fig. 6. A diagram of the ‘carrying sound’ circuit

Fig. 7. The transmitter’s circuit

Fig 8. The stereo plug
The receiver

1. Connect the two wires from the solar panel’s output to the 3.5 mm stereo plug or socket of the speakers using two alligator clips (figure 9a,b). Your circuit should look like the one in figure 10.

About what happens

The flashlight batteries provide a strong but constant direct current (DC) to the LEDs. As a result, the LEDs glow with a fixed brightness. When the mp3 player is turned on, it adds a weak but fluctuating electrical signal to the constant current from the battery. The LEDs flicker in sync with the output from the player. The stronger battery current of the flashlight is added to the weaker signal from the player (the capacitor protects the player from being overheated by the input DC). These fluctuations are picked up by the solar panel and are converted into electrical pulses that are turned back into sound by the speaker. This whole process is amplitude modulation (AM). It is the same principle used for transmitting AM radio signals.

A switch activated by the solar wind

Materials

- 470 Ω resistor
- 2 1N4001 diodes
- 1 2N3904 transistor
- 1 CD4069 inverter gate chip containing a U1A gate
- 4.5 V battery or 3-12 V DC power supply unit
- 1 relay coil (3-12 V depending on power supply) with one NC contact
- 1 green LED (as an indicator)
- 2 alligator clips
- One small breadboard

Procedure

1. Construct the circuit in figure 11; the result will look something like figure 12. In this circuit, an optional small piece of aluminium foil has been attached to the wire. This piece of foil plays the role of an antenna (the charge receiver conductor) to increase the sensitivity of the switch.

2. Use two alligator clips to connect the 4.5 V battery (or the power supply) to the corresponding red and black wires (figure 12). The green indicator LED turns on.

3. Interconnect this circuit to the ‘sound carrying’ circuit from box 1. This can be done in one of two ways:
   a. In series with the transmitter circuit⁶ (to show the effect of the solar wind on the circuit in a satellite that is responsible for transmitting the signal);

Fig. 12. The switch circuit that is activated by the solar wind

Fig. 13a. The switch circuit is connected to the transmitter

Fig. 13b. The diagram of the circuit presented in figure 13a
b. In series with the receiver circuit\(^7\) (to reflect the effect of the solar wind on the circuit in a satellite that is responsible for receiving the signal from another satellite or from the ground station).

To do so, insert the switch circuit (using the wires S\(_1\) and S\(_2\) shown in figure 12) to the transmitter or receiver as in Figures 13 and 14.

4. Turn the circuit on and move the charged stick towards and away from the circuit and note what happens.

**About what happens**

The circuit is in fact a switch triggered by the charges on the cardboard tube of the Fun Fly Stick. When the stick approaches the circuit, the induced electric charge turns on the relay and interrupts transmission\(^6\): according to our scenario, the solar wind has just hit a satellite and the transmission of the World Cup final has stopped. As soon as you turn off the charge, the relay turns off too, and the transmission resumes: the damage experienced by the satellite is negligible and reversible.
